

TIPS

for

accurately measuring blood pressure

Inaccurate blood pressure measurements can result from patient positioning errors. The following evidence-based tips can help ensure accurate blood pressure readings and improve patient care.

1

Ask the patient if they need to empty their bladder.

2

Let the patient relax for a minimum of five minutes before taking blood pressure measurements. Don't have a conversation as talking or active listening can increase the reading.

3

Place the correct size cuff on a bare arm.

4

Make certain the patient's arm is supported (at heart level) on a level surface. Legs should be uncrossed and back supported.

5

If initial blood pressure is elevated, obtain a confirmatory measurement.

- Repeat above steps.
- Ensure the patient has an empty bladder.
- Ensure the patient has rested quietly for at least five minutes.

Accurate blood pressure measurement is a HEDIS measure and ensures quality patient care!
